Accepted 23 March, 2019

The aim of this study is to investigate multi-drug resistance in *A. baumannii* strains that was isolated from clinical samples of three highly large hospitals in Tehran-Iran. This descriptive-cross sectional study was performed in three large hospitals in Tehran on 70 samples of *Acinetobacter* which were isolated from patients during April to November 2010. After identifying the species level by using culture and biochemical methods, in order to determine sensitivity of 50 isolates of *A. baumannii* to 13 antibiotics, standard methods according to CLSI guidelines were performed. In this study, resistance to three or more of three classes of antibiotics multidrug resistance was defined. In this study, 50 *A. baumannii* strains, 12 *A. lwoffii* strains and other *Acinetobacter* species were isolated from patients. The majority of isolates were from blood specimens. Isolates of *A. baumannii* showed the highest resistance to cefepime, ceftazidime, aztreonam, norfloxacin, ofloxacin, ciprofloxacin and amikacin. Tobramycin and meropenem considered as effective drugs in this study. Multi-drug resistance in these strains was respectively 55.4%. Multi-drug resistant *Acinetobacters* are growing and considered as important threat for hospitalized patients, so change in consumption patterns of antibiotics and control of hospital infections seems to be necessary.

Key words: *Acinetobacter baumannii,* nosocomial infection, multi-drug resistance, antibiogram.

INTRODUCTION

The genus Acinetobacter comprises Gram negative, oxidase negative, strictly aerobic and non motile bacteria. Various species of Acinetobacter are widespread in nature. They can be recovered from virtually all samples obtained from soil, surface water, human skin, food and waste (Gaynes et al., 2005; Leung et al., 2006; Peleg et al., 2008).

The genus known as Acinetobacter has significant taxonomic modification over last 30 years. *Acinetobacter baumannii* is the most common species that isolates from patients and other species such as *A. lwoffii, A. Johnsonii,* and *A. haemolyticus* are rarely isolated from patients (Peleg et al., 2008).

Nowadays, due to *A. baumannii* significant clinical properties and its ability to achieve drug resistance, it considered as one of the microorganisms that threaten antimicrobial medication. *Acinetobacter baumannii* causes nosocomial infections such as bacteremia, urinary tract infections and secondary meningitis, but it has prominent role in creation of hospital pneumonia especially pneumonia that acquired in upper respiratory tract in patients that hospitalized in intensive care units (ICU) (Anstey et al., 2002; Dijkshoorn et al., 2005; Fournier and Richet, 2006; Peleg et al., 2008; Rizos et al., 2007; Villers et al., 1998).

Different studies demonstrated that various species of *A. baumannii* are resistant to wide range of antibiotics. Spread of multi-drug resistant *A. baumannii is* not limited to hospitals of one city, but is also important in national

scale (Metan et al., 2007; Unal et al., 2005; Wisplinghoff et al., 2007; Wroblewska et al., 2007). Since several factors causing resistance in *A. baumannii*, treatment of infections caused by this organism should be based on perfect antibiotics sensitivity tests, therefore having information regarding the prevalence and pattern of bacterial resistance to these drugs is important (Halstead et al., 2007; Scott et al., 2007; Van Dessel et al., 2004). In this study is investigation of multi-drug resistance in *A. baumannii* strains that isolated from clinical samples from three large hospitals in Tehran-Iran.

MATERIALS AND METHODS

This descriptive-cross sectional study was conducted from April to November 2010. Five hundred samples of blood, respiratory sections, urine, skin sores, and trachea were collected from patients of three large hospitals of Imam Khomeini, Milad, Baqiyatallah and transferred to the laboratory by BHI broth medium.

In the laboratory each sample was cultured on blood agar and MacConkey agar (Merck Co., Germany) and incubated for 24 h in 37°C. Blood specimens was cultured in Trypticase Soy Broth (TSB) (Merck, Germany) and sub-cultured on chocolate agar. After 24 h, with direct examination (Gram staining) presence of gram negative coccobacillus was confirmed by the microscopic approach. In order to recognize different species of Acinetobacter, all suspected colonies were identified by colonial morphology, Gram-staining, positive catalase, negative oxidase, growth in 37 and 42°C and other biochemical reactions.

After identification of Acinetobacter species, in order to determine the drug resistance phenotype, disk diffusion method as recommended by clinical laboratory and standards institute (CLSI) was performed. In this study 13 different antibiotic disks from Oxoid Ltd. (Basingstoke, UK) were used which included amikacin (30 µg), ampicillin/sulbactam (10/10 µg), aztreonam (30 µg), cefepime (30 µg), ceftazidime (30 µg), ciprofloxacin (5 µ), gentamycin(10 µg), imipenem (10 µg), meropenem (10 µg), norfloxacin (10 µg), ofloxacin (1 µg), piperacillin / tazobactam (100/10 µg), tobramycin (10 µg). In addition, the antibiotic potency of the disks was standardized against the reference strains of *E. coli* (ATCC 25922) as negative control and the reference strain of *A. baumannii* (ATCC 19606) as positive control were used.

It is to say according to studies, isolates of *A. baumannii* that show resistance to three or more than three categories, including quinolone antibiotics (ciprofloxacin), broad spectrum cephalosporins (ceftazidime and cefepime), combined lactam/lactamase inhibitor(Ampicillin/sulbactam), aminoglycosides (amikacin, tobramycin) and carbapenems(imipenem, meropenem) considered as multi-drug resistant strains. Finally, for statistical analysis, data were entered into a database using SPSS 16 for Windows (SPSS Inc., Chicago, IL) and then, results by using Chi-square test were analyzed.

RESULTS

During this study, a total of 70 samples of Acinetobacter were isolated from 500 collected samples. Fifty samples of patients were identified as *A. baumannii* (71%), 12 samples were *A. lwoffii* (17.1%) and 8 samples (11.4%) were other Acinetobacter species.

Results showed that 50 samples of *A. baumannii* were isolated from 19 blood samples (38%), 15 trachea tube aspiration samples (30%), 6 wound samples (12%), 4 urine samples (8%), 1 oral sample (2%), and 5 samples (10%) had unknown origin.

The majority of strains were isolated from ICUs (20/50) and the remaining strains were from infectious ward (15/50), emergency ward (10/50) and other wards.

In this study approximately all samples were resistant to ceftazidime and cefepime and high resistance to aztreonam, norfloxacin, ciprofloxacin, amikacin, imipenem, gentamycin, and ampicillin-sulbactam were observed. Tobramycin and meropenem considered as effective drugs in this review. (In Table 1 patterns of antibiotic resistance in *A. baumannii* are showed).

Results of this study showed that 27 samples of *A. baumannii* (54%) are resistant to three or more than three antibiotics (Table 2) and 16 samples (32%) showed resistance to two antibiotics. Also none of resistant strains were showed complete resistance to all antibiotics.

Conclusion

Acinetobacter baumannii is an important opportunistic pathogen to high virulence. It is responsible for severe nosocomial infections over the last 30 years. This bacterium, particularly multi-drug resistant strains has been implicated as the cause of serious infectious disease in different parts of the hospitals and treatment of such infections because of their broad resistance to antibiotics is difficult (Anstey et al., 2002; Gaynes et al., 2005; Leung et al., 2006; Peleg et al., 2008). Moreover, since environmental factors and different patterns of antimicrobial agents play important role in creation and expansion of these strains in different parts of the world, in this study, the incidence of multi-drug resistant *A. baumannii* from clinical samples of three hospitals in Tehran-Iran was performed.

In this investigation 71.5% of isolates were *A. baumannii* and 28.5% were identified as A*. lwoffii* and other Acinetobacter species. A similar finding was also observed by Constantiniu and colleagues during years 2001 to 2004. They from 24 clinical isolates, 71% *A. baumannii* and 29% *A. lwoffii* were detected (Constantiniu et al., 2004).

Hujer et al. (2006) in their study that was conducted on military and civilian patients in Iraq and Afghanistan reported that 15% of the strains were resistant to all nine antibiotics which were tested and 89% of strains showed resistance to at least three antibiotic classes. In their study more than 90% of isolates were resistant to ciprofloxacin, less than 80% to cephalosporins with a broad spectrum, 40% to ampicillin-sulbactam, 20% to imipenem and 81% to at least one of the aminoglycosides (amikacin or tobramycin) (Hujer et al., 2006). In this study, more than 90% of isolates to

Table 1. Frequency of antibiotic resistance in *A. baumannii* isolates.

Antibiotic	Sensitivity patterns (%)		
	Resistant	Intermediate	Sensitive
Cefepime	96	4	0
Ceftazidime	96	4	0
Aztreonam	95	3	2
Norfloxacin	95	1	4
Ofloxacin	88	4	8
Ciprofloxacin	88	4	8
Amikacin	85	5	10
Imipenem	76	2	22
Gentamycin	61	3	36
Ampicillin-sulbactam	59	3	38
Piperacillin-tazobactam	40	8	52
Meropenem	31	4	65
Tobramycin	26	2	72

Table 2. Frequency of multi- drug resistance in *A. baumannii*.

Parameter	Resistance to one or several antibiotics					Total
Number of antibiotics	1	2	3	4	>4	50
Number of isolates resistant *A. baumannii*	7	16	13	5	9	

ciprofloxacin, ofloxacin, and cephalosporins (ceftazidime and cefepime), 76% to imipenem, 59% to ampicillin / sulbactam, and less than 35% to meropenem and tobramycin were resistant (Table 1). Also in this study more than 50% of isolates were resistant to at least three antibiotic classes (Table 2). Differences observed between two studies could be due to methods and resistance patterns that are influenced by environmental factors and antimicrobial patterns which were used. Necessary to say, international travels are also important in development of multi-drug resistant strains.

Acinetobacter strains with antibiotic resistance have been reported from all around the world (Brink et al., 2007). In the study in year 2003 that performed by Ayan and colleagues, of 52 strains, all isolates were resistant to piperacillin, piperacillin-tazobactam, ticarcillin-clavulanic acid, cefepime, cefotaxime, ceftazidime, ceftriaxone, gentamycin and resistant to tobramycin , ciprofloxacin, ampicillin-sulbactam, co-trimoxazole, and amikacin that results highly conform with results of this research (Ayan et al., 2003).

Rahbar and colleagues in the year 2005 to 2006 were determined that, *A. baumannii* shows high percentage of resistance to ceftriaxone (90.9%), piperacillin (90.9%), ceftazidime (84.1%), amikacin (85.2%),and ciprofloxacin (90.9%) that results partly conform with results of this research. They had also conducted that imipenem was the most effective agent against these organisms (resistance 4.5%) that is in conflict with our results (Rahbar et al., 2010).

In a study that in year 1998 to 2001 was conducted by Karlowsky et al., 90% of *A. baumannii* strains were sensitive to meropenem, but in this investigation, only 44% of strains showed resistance to meropenem and usage of this antibiotic with tobramycin could be more effective against *A. baumannii* strains (Karlowsky et al., 2003).

In a study that performed by Hoe Koo et al in years 2007 to 2008, they determined amikacin as the most effective drug among nine antimicrobial agents, unlike, in this study tobramycin and imipenem were the most effective agents among 11 antimicrobial agents which were used (Hoe Koo et al., 2010).

Overall results indicate that among common *Acinetobacter* species, *A. baumannii* is more responsible for nosocomial infections and more than 50% of strains are multi-drug resistant, so control of hospital infections seems to be necessary among the three hospitals which were investigated. In this regard, in response to uncontrolled use of antibiotics, multi-drug resistant *A. baumannii* in hospital environment increased, so control of antibiotics usage in hospitals play an important role in preventing the emergence of such strains and infections caused by them.
